1-1. Hypervalent?

"Molecules containing elements of Group 15 - 18 bearing more electrons than the octet in the valence shell are described as hypervalent molecules."

$$\lambda^{5}$$
-iodane λ^{4} -sulforane λ^{4} -sulfor

 λ^{o} = the bonding number to an atom.

Mr. Kojima, B4 literature seminar.

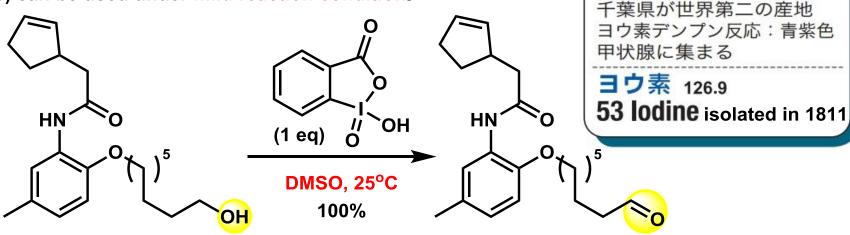

1-2. Features

The important and significant factors of multivalent organoiodine compounds;

1) are made from relatively inexpensive commercial precursors.

- 2) tend to be selective in their reaction.
- 3) can be used under mild reaction condition.

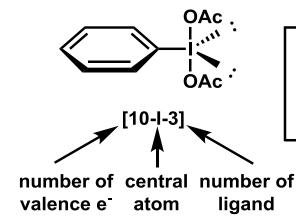

4) I(III) resembles the reactivity characteristics of Hg(II), TI(III) and Pb(IV) without the toxic and environmental problems.

1-3. Structure

Aryl- λ^3 -iodanes (ArlL₂)

- Ar-I bond is a typycal bond with sp² hybridization.
- I-L bonds are the hypervalent bonds.
- The most electronegative ligands reside in the apical positions.

The hypervalent molecular orbitals

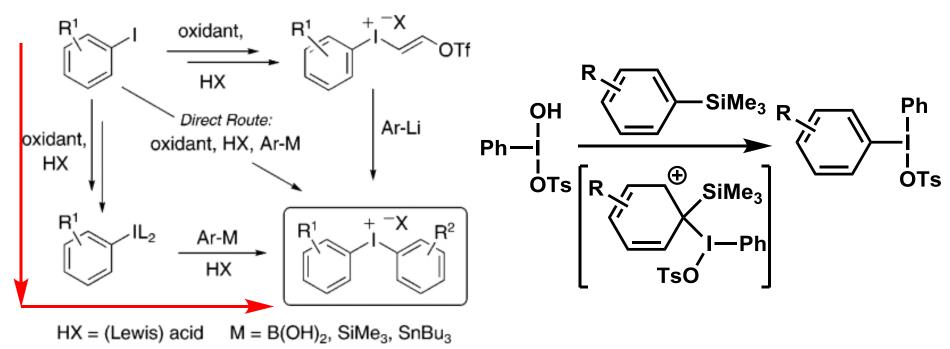

electrophilicity at iodine

2 e⁻ come from iodine and 1 e⁻ comes from each L, creating a 4 e⁻, 3 center bond.

1-4. Synthesis

3 routes for synthesis iodonium salt

G.F. Koser, et al., J. Org. Chem. 1980, 45, 1543.

1-5. Reactivity

1) Reaction with various nucleophiles

by initial Nu-I bond formation and release of one of ligands.

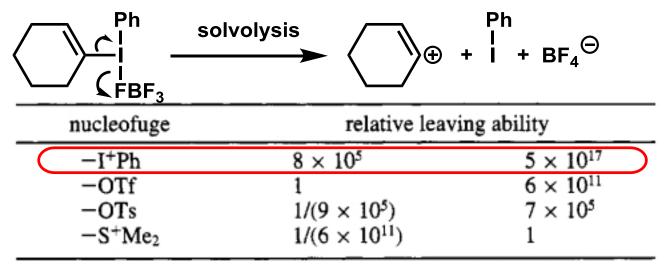

$$Nu^{-} + Ar-IL_{2} \longrightarrow Ar-I(Nu)L \longrightarrow Nu-L + Ar-I$$

$$-L^{-}$$

$$reductive elimination$$

2) Reaction with catalytic metal

- A more electrophilic metal catalyst should facilitate the metalation process [Pd(II) to Cu(III)]
- lodine(III) reagents could oxidize Cu(I) to Cu(III)Ar. These intermediates should be highly electrophilic
- Can a C3 to C2 migration of the C-Cu bond be controlled to in order to determine the site selectivity?

Pd(II) is a d⁸ metal and is electrophilic Cu (III) is a d8 metal and should be highly electrophilic
