discussion 1: Chemical shift

## Discussion 1: Chemical shift

The compounds with tricyclo-[3.3.1.0 ${ }^{2,8}$ ]-3,6-diene skeleton, so called barbaralyl skeletone, have unique NMR spectral features.

Table 1. ${ }^{1} \mathrm{H}$ NMR spectrum of $1-\mathbf{8}^{2)}$

| No. | at $-70^{\circ} \mathrm{C}(\delta)^{*}$ | at $25^{\circ} \mathrm{C}[\delta$, multi, $J(\mathrm{~Hz})]$ | $\Delta$ |
| :---: | :---: | :---: | :---: |
| 1 | 2.46 | $2.60(\mathrm{t}, 6.5)$ | +0.14 |
| 2,8 | 2.91 | $\underline{4.20}(\underline{\mathrm{t}, 7.0})$ | +1.29 |
| 3,7 | 5.71 | $5.69(\mathrm{t}, 7.3)$ | -0.02 |
| 4,6 | 5.92 | $\underline{4.20} \underline{(\mathrm{t}, 7.0)}$ | -1.72 |
| 5 | 2.91 | $2.60(\mathrm{t}, 6.5)$ | -0.31 |
| * signal patterns were not mentioned |  |  |  |

At $-70^{\circ} \mathrm{C}$, the peak of each proton is quite normal. However, at $25^{\circ} \mathrm{C}$, some peaks drastically shifted $(\mathrm{H} 2$ and $8, \mathrm{H} 4$ and 6 ), and H 1 and H 5 showed the same peak patterns.

$1-8$ shows unique ${ }^{1} \mathrm{H}$ NMR spectrum because it can change its structure by Cope rearrangement. At $-70{ }^{\circ} \mathrm{C}$, this rearrangement is slow that H 2 and H 4 can be distinguished. As the temperature increases, this rearrangement proceeds at time-scale of NMR, these protons cannot be distinguished. Finally, at $25^{\circ} \mathrm{C}, \mathrm{H} 1$ and H 5 showed the same peak pattern, as well as four protons (H2,4,6,8) showed the same peak pattern.

$$
\delta 3.55(\mathrm{~d}, \mathrm{~J}=3.4 \mathrm{~Hz})
$$

Since 1-2 has barbaralyl skeletone, the rapid Cope rearrangement of 1-2 proceeds like 1-8. Thus, there is in equilibrium between 1-2 and ent-1-2 at room temperature, and it displays a spectrum consistent with a fluxional structure with averaged resonances and chemical shifts.

Appendix:

Unlike 1-2 and 1-8, fluxional structure was not observed in 1-7. This is because the size of OTIPS is too large to proceed Cope rearrangement. So normal chemical shift are observed in this compound.

Answer:

$\xrightarrow{-\mathrm{TIPSCI}}$

2-13

- PhCN

2-14

A

2-16

$\mathrm{Cu}^{\prime} \mathrm{Cl}, \mathrm{LiCl}$

of $\mathbf{A}$, suggesting that 2-16 was generated in the reaction.

Discussion 2: Shapeshifting anions
2.1. Experimental results

2-23-H

TIPSOTf

2-11
73\%

2-24
not obtained

Results (a) and (b) suggest that there exist at least 5 intermediates (2-25-A to E) from deprotonation of 2-1 or 2-3. Based on the result (c), an equilibrium should exist between the five isomers, and equilibrium is shifted when different substituent is introduced ( $X=\mathrm{H}: \mathbf{2 - 2 5 - B}$ and 2-25-E are in favor. $X=S P h: \mathbf{2 - 2 5 - D}$ is in favor.)

### 2.2. Computational calculation

For better understanding, the authors employed DFT calculations for each isomer.
Relative free energy differences of isomeric anions:

|  | $\Delta \mathrm{G}^{\circ}(\mathrm{kcal} / \mathrm{mol})$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| X | $\mathbf{2 - 2 5 - B}$ | $\mathbf{2 - 2 5 - C}$ | $\mathbf{2 - 2 5 - \mathrm { D }}$ | $\mathbf{2 - 2 5 - E}$ |
| SPh | 0.0 | +7.1 | $\underline{-4.0}$ | +0.4 |
| OMe | 0.0 | +8.3 | $\underline{-6.6}$ | $\mathbf{- 3 . 0}$ |
| F | 0.0 | +9.2 | $\underline{-3.3}$ | $\underline{-3.3}$ |
| H | 0.0 | +8.2 | +0.3 | $\underline{-0.9}$ |
| CN | 0.0 | +4.5 | -1.7 | $\underline{\mathbf{- 2 . 5}}$ |

* calculated at B3LYP-D3(BJ)/6-311+G(d,p)/PCM(THF)//B3LYP-D3(BJ)/6-31+G(d,p)/PCM(THF) at 195 K

Calculations showed that the chelating form is the most stable conformer of 2-25-D. When $X$ is an electron-donating substituent (e.g., SPh, OMe), the stabilizing effect of chelation is enhanced, making 2-25-D the most stable of the five isomers.
On the other hand, when $X$ is an electron-withdrawing substituent, this stabilizing effect is weaken, making 2-25-D less stable. As a result, 2-25-E became the most stable conformer ( $X=C N$ ).
2.3. In case of 2-1 $(X=S P h)$

2-25-A-SPh
(disfavored)
(allylic anion)

2-25-B-SPh
(disfavored)
$\Delta \mathrm{G}^{\circ}=0.0 \mathrm{kcal} / \mathrm{mol}$

2-25-C-SPh
(disfavored)
$\Delta G^{\circ}=+7.1 \mathrm{kcal} / \mathrm{mol}$

2-25-D-SPh
(favored)
$\Delta G^{\circ}=-4.0 \mathrm{kcal} / \mathrm{mol}$

2-25-E-SPh
(unfavored)
$\Delta G^{0}=+0.4 \mathrm{kcal} / \mathrm{mol}$
no further reaction proceeds

2-2

2-22
$\mathbf{2 - 2 5 - A}, \mathbf{2 - 2 5 - B}$ and 2-25-C are thought to be disfavored due to unstable allylic anion (A) or large steric repulsion between highlighted atoms of cyclopropane ( $\mathbf{B}$ and $\mathbf{C}$ ).
$\mathbf{2 - 2 5 - D}$ is more favored in comparison with 2-25-E, because potassium enolate can be stabilized by adjacent carbonyl groups in the presence of electron donating group, SPh.
Calculation suggests that 2-25-D is by far the most stable isomer, so the anions are present almost only in the form of 2-25-D-SPh during the reaction, yielding 2-2 or 2-22 as a major product.
2.4. In case of 2-3 $(\mathrm{X}=\mathrm{H})$

2-25-A-H
(disfavored)
(allylic anion)

2-25-B-H
(favored) $\Delta G^{\circ}=0.0 \mathrm{kcal} / \mathrm{mol}$

2-25-C-H
(disfavored)
$\Delta G^{\circ}=+8.2 \mathrm{kcal} / \mathrm{mol}$

2-25-D-H
(favored) $\Delta G^{\circ}=+0.3 \mathrm{kcal} / \mathrm{mol} \quad \Delta \mathrm{G}^{\circ}=-0.9 \mathrm{kcal} / \mathrm{mol}$
$\mathbf{2 - 2 5 - B}, \mathbf{2 - 2 5 - D}$ and 2-25-E are in favor. Calculation shows that there are only small energy differences among these 3 isomers, so there are 3 isomers in the reaction mixture.

The $\alpha$ and $\beta$ faces of enolate are shielded in all isomers. Among them, the $\beta$-face of 2-25-B-H is relatively uncrowded because it has only one $\mathrm{sp}^{2}$ carbon (the others have two or three $\mathrm{sp}^{2}$ carbons). SiOTf is too large to access to the other faces, so silyl etherification proceeds only from the $\beta$-face of 2-25-B-H, with 2-11 ( $\mathrm{X}=\mathrm{TIPS}$ ) or 2-20 ( $\mathrm{X}=\mathrm{TBS}$ ) being obtained as a major product.

### 2.4.2. Protonation

Compared to SiOTf, proton is small, so protonation can be proceed from all of 3 isomers. 2-24-E-H is the most stable conformer, but the protonation is relatively slow because of steric hindrance. 2-24-B-H is the second most stable conformer, and the protonation is faster than from 2-24-E-H. As a result, 2-21 was obtained as well as 2-23. (If $\Delta \mathrm{G}^{\circ}=0.9$, the ratio of $\mathbf{2 - 2 4 - B}-\mathrm{H}: \mathbf{2 - 2 4 - E}-\mathrm{H}$ would be $18: 82$ ).
