Hongo Campus .................................................................... 53
The history of the Graduate School of Pharmaceutical Sciences goes back to 1873, when the First University District Medical School, precursor of the University of Tokyo Faculty of Medicine, established a five-year pharmaceutics program (two years of preparatory study followed by three years of pharmaceutical coursework). The program continued to operate under the aegis of the Faculty of Medicine until 1958, when an independent Faculty of Pharmaceutical Sciences was established. At that time, it comprised just eight laboratories. Today we have twenty laboratories in our core program alone. Because I was born the same year the independent faculty opened, I tend to view its development in relation to my own milestones.

Research and education at the graduate school span the entire spectrum of pharmaceutical sciences, from pharmaceutical chemistry, pharmaceutical biology, and pharmaceutical physics to medical pharmaceutics, social pharmacy, and drug discovery. Generally speaking, though, our program is distinguished by its emphasis on basic life science research. Such research lays the foundation for the development of new drugs through the discovery of new molecular functions and life phenomena and the development of new reaction, synthesis, and analytical technologies.

Creating new drugs involves marshaling information and insights from multiple fields, and for this, interdisciplinary research is essential. This is why our staff includes not just specialists in pharmaceutics per se but also experts in various associated fields. Of the professors who head our main laboratories, 12 have degrees in pharmaceutics, 4 in natural science or engineering, and 2 in medicine or dentistry (as of April 2020). While leveraging their own individual assets to the full, they work together as a unified team to fulfill the School’s educational and research mission.

There has been a tendency of late to belittle basic research as inferior to “research that is useful to society.” But there are still undiscovered natural phenomena and avenues of research that lie beyond our imagination. Time and again, pure scientific curiosity has opened up new and fruitful fields of study. Basic research into the CRISPR-Cas9 system, a kind of immune mechanism by which bacteria eliminate viruses, paved the way for the development of CRISPR gene editing, an immensely useful technology. Our students and faculty do outstanding research by investigating the basic life sciences as their curiosity impels them, and they have fun in the process. I believe that all top-caliber basic life science research is ultimately useful.

Along with such basic research, the graduate school is channeling serious resources into the training of pharmacists to meet society’s need for professionals to support the proper use of pharmaceuticals, mindful of recent trends in advanced medical care and the separation of prescribing and dispensing. As a result, our program continues to rank first in the nation in the percentage of new graduates who pass the national licensing examination for pharmacists. On the other hand, only about 10% of those completing the six-year training program go on to the four-year doctoral program in pharmacy—far short of the 40% who advance from the master’s course in pharmaceutical sciences to the doctoral program in that department (three years). Our challenge now is to boost enrollment in the doctoral program in pharmacy and create a fertile environment for the training of pharmacists with the advanced expertise and research skills to lead the profession.

At the Graduate School of Pharmaceutical Sciences, we are committed to improving the health and welfare of humankind through outstanding achievements in basic life science research and the education of top-flight life science researchers and leading pharmacists. We are counting on your support for that mission going forward.

FUNATSU Takashi
Dean
Graduate School of Pharmaceutical Sciences
Faculty of Pharmaceutical Sciences
Department of Pharmaceutical Manufacturing was established in Daiichi-Daigaku-Ku Igakko (The First University District Medical School) in Kanda Izumicho, Tokyo.

Daiichi-Daigaku-Ku Igakko was renamed as Tokyo-Igakko (Tokyo Medical School).

Tokyo-Igakko was moved to Hongo, Tokyo.

Tokyo Daigaku, The University of Tokyo was established.

Tokyo-Igakko was renamed as the University of Tokyo Faculty of Medicine.

The organization of pharmaceutical education began with the establishment of Pharmaceutical Institute (later Department of Pharmaceutical Manufacturing in the Faculty of Medicine). For the first 10 years, instruction was given by foreigners and in particular a Dutch chemist Dr. J. E. Eijkman. He left a large amount of fine work in the study of components of various domestic medicinal plants.

The University of Tokyo was renamed as Imperial University and the name of the Department of Pharmaceutical Manufacturing in the Faculty of Medicine was changed to the Department of Pharmacy in the Imperial University Medical College.

Japanese who had returned from studies in Germany took over the education of students, carried out valuable investigations of their own, and also established the ground for pharmaceutical organic chemistry in Japan.

The University of Tokyo was renamed as Imperial University and the name of the Department of Pharmaceutical Manufacturing in the Faculty of Medicine was changed to the Department of Pharmacy in the Imperial University Medical College.

The Department of Pharmacy separated from the Faculty of Medicine and became an independent faculty as the Department of Pharmaceutical Sciences, the Faculty of Pharmaceutical Sciences.

The Department of Pharmaceutical Technochemistry was established.

The Graduate School of Pharmaceutical Sciences, The University of Tokyo was established. (Department of Pharmaceutical Sciences and Department of Pharmaceutical Technochemistry)

The Research Institute for Chemical Hazards was established.

The Experimental Station for Medicinal Plant Studies was established.

The Research Institute for Chemical Hazards was abolished, and instead the Department of Pharmaceutical Life-Science was established.

Two departments were unified into the Department of Pharmaceutical Sciences.

The graduate school was reorganized along with the new system, "Graduate School Priority System" and reformed into three Departments, that is Pharmaceutical Chemistry, Pharmaceutical Biology, and Pharmaceutical Technology. Although the Faculty’s emphasis of education is shifted from the Undergraduate Program to the Graduate Program, most of the faculty members also continue undergraduate education.

Clinical Pharmacy Course was established in the Master’s Program.

Pharmaceutical Sciences Research Building was constructed.

Following the revision of the School Education Act, the Faculty of Pharmaceutical Sciences started a new program with Department of Pharmaceutical Sciences (4-year program) and Department of Pharmacy (6-year program).

Department of Integrated Pharmaceutical Sciences was added to the Graduate School, which consists of total 4 departments.

The former 4 departments in the Master’s Program were abolished and the Department of Pharmaceutical Sciences was established. Clinical Pharmacy Course was abolished.

The former 4 departments in the Doctoral Program were abolished. Department of Pharmaceutical Sciences and Department of Pharmacy were established in the Doctoral Program. Dual Speciality Course on Pharmacist Education was established.

( ) Female students

( ) Numbers indicate MEXT Scholarship Students
Pharmaceutical sciences is an academic field that covers development of pharmaceuticals and their applications. The field encompasses fundamental, life-related substances and their interactions with life; using organic chemistry, physical chemistry, and biochemistry as a base, upon which is built a wide range of research fields, including interdisciplinary areas. With these parallel 6-year and 4-year programs, the Faculty of Pharmaceutical Sciences not only provides traditional training in basic research for drug discovery but also offers some courses in advanced training for pharmacists. (Graduates of the Department of Pharmacy are qualified for the national examination for pharmacists.) No differentiation is made between the Departments of Pharmacy and Pharmaceutical Sciences from the College of Arts and Sciences until entering higher education, allowing students to gain an ample understanding of research content before deciding between the two departments in their fourth year.

Our doctoral program in the Department of Pharmaceutical Sciences, established in 2012, also provides a Dual Specialty Course on Pharmacist Education allowing students to be qualified for the national examination for pharmacists. (This is provided for students who enter the University of Tokyo by the 2017 school year and graduate from the Department of Pharmaceutical Sciences, Faculty of Pharmaceutical Sciences.)
Pharmaceutical sciences is an academic field that covers development of pharmaceuticals and their applications. The field encompasses fundamental, life-related substances and their interactions with life; using organic chemistry, physical chemistry, and biochemistry as a base, upon which is built a wide range of research fields, including interdisciplinary areas. With these parallel 6-year and 4-year programs, the Faculty of Pharmaceutical Sciences not only provides traditional training in basic research for drug discovery but also offers some courses in advanced training for pharmacists. (Graduates of the Department of Pharmacy are qualified for the national examination for pharmacists.) No differentiation is made between the Departments of Pharmacy and Pharmaceutical Sciences from the College of Arts and Sciences until entering higher education, allowing students to gain an ample understanding of research content before deciding between the two departments in their fourth year.

Our doctoral program in the Department of Pharmaceutical Sciences, established in 2012, also provides a Dual Specialty Course on Pharmacist Education allowing students to be qualified for the national examination for pharmacists. (This is provided for students who enter the University of Tokyo by the 2017 school year and graduate from the Department of Pharmaceutical Sciences, Faculty of Pharmaceutical Sciences.)
**Department of Pharmaceutical Sciences**

Four-year program

Taking on the goal of the previous Department of Pharmacy curriculum, the Department aims to educate high-quality researchers, focusing on developing personnel in the fields of drug discovery and basic life-science research. With a capacity of 90 percent of all students, the Department offers graduates a two-year master’s program, then to a three-year doctoral program. The curriculum is nearly identical to the Department of Pharmacy until the third year, allowing students to experience on-the-ground medical treatment even if they intend to pursue research.

**Department of Pharmacy**

Six-year program

In response to the advancement of medical care, the purpose of the establishment of this department is to train and develop high-quality pharmacists. One large difference from the Department of Pharmaceutical Sciences is that the program includes six-month practical hospital/pharmacy training. The Department’s capacity is 10 percent of all students, providing high-quality pharmacy education to a small number of students, aiming to create personnel who will be able to lead this field. Six-year pharmacy departments are well over capacity across all of Japan; to avoid disruption, the University of Tokyo’s Faculty of Pharmacy will collaborate with the University of Tokyo Hospital and local pharmacies in order to provide smooth, uninterrupted practical training.

**Faculty Curriculum**

Lectures and practicums lie in the center of the education at the Faculty of Pharmaceutical Sciences. They are provided to students in order for them to acquire the broad knowledge and the perspectives of pharmacists, as well as to have a clear view when they decide which field of pharmacy they should enter as specialists. One can say that lectures provided to faculty students are the essence of pharmaceutical sciences. Furthermore, reflecting the diversity in research areas in the Faculty of Pharmaceutical Sciences, the pharmacy practicums encompass a wide range of training areas. It is efficiently designed in a way that students will be able to put organic chemistry, physical chemistry, biochemistry and clinical pharmacy into practice. When students enter into their fourth year, each student will be allocated to a class of his/her own choice and will have opportunities to get hands-on experience in the cutting-edge pharmacy through the participation in research projects.

**Department of Pharmaceutical Sciences**

80 credits

(Compulsory: 62 credits, Elective: 18 credits or more)

**Department of Pharmacy**

120 credits

(Compulsory: 109 credits, Elective: 11 credits or more)

**2nd year: Autumn 1**

</table>
Organic Chemistry I 1 Students will learn the fundamentals such as stereochemistry, structural chemistry, reduction and oxidation. ④⑥

Physical Chemistry II 1 Lectures are aimed to allow students to understand important concept of thermodynamics, acquire the physicochemical perspectives and learn methods that are important in pharmaceutical sciences. ④⑥

Physiological Anatomy of Human Body 1 Students will learn the structures and functions of each organ (i.e., anatomy and physiology) as the basic knowledge for them to understand pharmacotherapy and pathophysiology. ④⑥

Physical Chemistry I 1 Students will aim to acquire the physiochemical concept by understanding quantum chemistry and spectroscopy. ④⑥

Introduction to Pharmaceutical Sciences 1 The outline, history and the future vision of pharmaceutical sciences will be explained in an easy to understand manner, allowing students to think about the relationship between pharmaceutical sciences and society in terms of industry and medical care. Moreover, students will learn some of the latest studies in the field of pharmaceutical sciences. ④⑥

Biostatistics 1 Students will receive lectures and practicums regarding statistical methods and experimental methods used for drug evaluations. 4 6

Graduate School of Pharmaceutical Sciences

Pharmaceutical education experienced major changes beginning with students entering in the 2006 school year. As a result, the University of Tokyo’s Faculty of Pharmaceutical Sciences established two new departments: The Department of Pharmaceutical Sciences, a four-year program designed to train researchers in basic drug discovery, and the Department of Pharmacy, a six-year program that qualifies graduates for the national examination for pharmacists. New graduate schools were also established based on student progression through their programs.

In April of 2010, we established a master’s program in pharmaceutical sciences for graduates of the four-year Department of Pharmaceutical Sciences program. This research program unites the four departments that previously existed, creating a single department instead.

In April of 2012, we established a doctoral program in pharmaceutical sciences for graduates of the master’s program (duration of program: three years), along with a doctoral program in pharmacy for graduates of the six-year Department of Pharmacy program (duration of program: four years). The doctoral program in pharmaceutical sciences also offers a Dual Specialty Course on Pharmacist Education to qualify four-year doctoral graduates for the national examination for pharmacists (Only applied to those students enrolled at the University of Tokyo in April, 2017 and graduated from the Department of Pharmaceutical Sciences, Faculty of Pharmaceutical Sciences).

Graduate School Curriculum

The main part of graduate school curriculum is "special research" through participations in research conducted in each laboratory. At the Graduate School lectures are targeted at students in master’s program/doctoral program(Department of Pharmacy). Those lectures are highly specialized, covering the latest information in the field, thus allowing them to be the world’s top class.

### 4th～6th year (Department of Pharmacy)

Laboratory of
Organic and Medicinal Chemistry

Synthesis of novel intelligent molecules which link chemical structures to biological functions in organic and medicinal chemistry

Research Topics

1. Synthesis of new compounds exhibiting characteristic structural features and properties, finally relevant to biological functions
2. New reactions to functionalize aromatic compounds based on designed superelectrophiles
3. Design and synthesis of intelligent molecules, which will have impacts on functions of membrane proteins
4. Computational modeling and simulations of organic and macromolecular systems

Our aims of researches emphasize on design and synthesis of structurally novel organic molecules, which are characteristic in terms of structural (bonding) features and intrinsic functions such as chemical reactivities and biological functions. Designs of such novel molecules are based on our finding new chemistry including ground-state stable non-planar amide peptides and nitrosamines, and structures of multiply positively charged molecules. We study nitrogen-pyramidal amides and related nitrosamines, i.e., molecules that take nonplanar structures, different from the common planar amides. We apply this chemistry to construction of molecules of highly ordered structures such as helix peptide mimetics stable in water. We also develop new chemistry involving dication or trication molecules and apply them as superelectrophiles to synthesize a variety of novel multifunctionalized aromatic compounds, which are pharmaceutically relevant. We are also creating chemical molecules, which will be useful to controlling biological events of membrane proteins such as ion channels, neurotransporters and G-protein-coupled receptors. These molecules also contribute to understanding the physiological functions of these membrane proteins. We combine all the experimental projects with computational chemistry, which will lead to deep understanding of the underling chemistry.
Laboratory of
Synthetic Natural Products Chemistry

H. Itoh
Project Assist. Prof.
K. Hagiwara

http://www.f.u-tokyo.ac.jp/~inoue/e_index.html

Research Topics

1. Development of new synthetic methodologies for total synthesis
2. Total synthesis of highly oxygenated polycyclic natural products
3. Total synthesis and functional analysis of ion channel-forming molecules
4. Total synthesis and functional analysis of antimicrobial molecules
5. Synthesis of new artificial molecules by modification of natural products templates

Total synthesis and functional analysis of biologically active natural products
The main theme of our research is the development of revolutionary catalyses facilitating new drug design and synthesis. In this direction, we would like to promote human health based on the catalysis development. Chemical synthesis in 21st century should be clean, robust, and concise, no matter how complex the target molecules are. The “ideal synthesis” will be only possible by new catalytic methodologies. Moreover, new catalyses will expand the diversity of readily available building blocks, leading to structurally novel artificial drug design. Sustainability based on new catalysis is another direction of our research. Specifically, we are interested in catalytic activations of small molecules such as H2 and O2.

Research Topics

1. Development of new catalysis to facilitate complex molecule synthesis
2. Clean, robust, and concise synthesis of pharmaceuticals and their leads
3. Catalytic H2 and O2 activation
4. Conceptually new approach to promote human health

The main theme of our research is the development of revolutionary catalyses facilitating new drug design and synthesis. In this direction, we would like to promote human health based on the catalysis development. Chemical synthesis in 21st century should be clean, robust, and concise, no matter how complex the target molecules are. The “ideal synthesis” will be only possible by new catalytic methodologies. Moreover, new catalyses will expand the diversity of readily available building blocks, leading to structurally novel artificial drug design. Sustainability based on new catalysis is another direction of our research. Specifically, we are interested in catalytic activations of small molecules such as H2 and O2.
We establish the mechanisms of natural product biosynthesis as a science in their own right, to construct a rational system for the production of new and useful substances

**Research Topics**

1. The biosynthesis and bioengineering of medicinal natural products (genome mining, engineered biosynthesis)
2. The enzyme biocatalysts (structure-function analysis, enzyme engineering, mechanistic studies)
3. The search for bioactive substances and isolation/structure determination

Natural organic compounds, prominent among which are antibiotics such as penicillin, are gifts from nature, and the benefits they have bestowed upon humankind as sources for the pharmaceuticals, etc., that maintain health is inestimable. In our laboratory, we study the process of biosynthesis of natural organic compounds produced by plants and microorganisms, using not only the foundation discipline of organic chemistry, but also incorporating the methods of biochemistry and molecular biology in an effort to understand the enzymes that catalyze each biosynthesis reaction and the functions and control mechanisms of the genes that govern their expression at the molecular level. In addition, we are expanding our research into “biosynthesis engineering,” by which rational systems for the biological production of new and useful substances can be designed and constructed, based on the mechanisms of biosynthesis that have been brought to light. We also are carrying out research on the mechanisms by which the bioactivity of natural products is expressed, while at the same time searching for natural products that are active in intracellular signaling.
Laboratory of
Advanced Elements Chemistry

Understanding of chemical phenomena at the atomic and electron levels and creation of a new science of materials through flexible construction of molecules

**Research Topics**

1. Development of advanced molecular transformation methods supporting materials science and life sciences (methodology development/synthetic chemistry)
2. Periodic table-traversing chemistry that transcends the frameworks of organic chemistry, inorganic chemistry, and metallic chemistry (elements chemistry)
3. Elucidation of the structural chemistry of intermediates and transitional states (physical chemistry, spectroscopy, theoretical calculation)
4. Design and production of materials founded on synthetic chemistry, spectroscopy, and computational chemistry (materials science/life sciences)

Our laboratory focuses on understanding the properties and phenomena of substances by “language of chemistry” such as molecules, atoms, and electrons (Seeing/Knowing); on developing reactions that manipulate the bonds between atoms completely in control (Designing); and on producing functional materials (Producing).

In our laboratory, we strive to develop technologies for the precise chemical conversion of tiny, tiny molecules less than 1 billionth of a meter in size (nanometer scale; nm). Thanks to recent advances in spectroscopy and theoretical calculation, it is getting possible to accurately predict and reproduce snapshots of the state of the electrons that form materials, as well as of reactions between molecules.

With the 3 methods, namely, synthetic chemistry, spectroscopy, and theoretical calculation as the pillars of our science, we expand upon elements chemistry in an interdisciplinary manner as we meet the challenges of elucidating life phenomena and creating a new materials science.

Developing new reactions and designing/producing new materials based on computational chemistry and theoretical chemistry (Adopted for the cover of Chemistry: A European Journal)

Life sciences and materials science that open new frontiers in basic organic chemistry and elemental chemistry
Laboratory of Chemistry and Biology

"Chemical Biology" and "Chemical Medicine" in order to promote life science research and to develop novel medical tools

Research Topics

1. Fundamental photophysical and photochemical research to establish rational design principle for novel chemical tools
2. Theoretical design, synthesis and biological application of novel chemical tools, including sensor molecules and signal perturbation techniques for cellular signaling molecules, such as Ca^{2+} ion, reactive oxygen species, or various enzymes
3. Development of chemical tools, e.g., MRI probe and fluorescent probe, for diagnostic imaging and their in vivo application
4. Clinical use of our newly developed fluorescence probes for rapid imaging of tumor with human clinical fresh specimens
5. Research on drug discovery: Searching for novel lead compounds that control disease-related proteins, and development of high-quality screening systems

Our laboratory conducts research on the analysis and perturbation of dynamic living systems, using chemistry as a powerful tool. One of the important goals in modern life sciences is to elucidate the dynamic behaviors of biomolecules in situ in the living cells/organisms. So far, our laboratory has succeeded in developing bioimaging probes/other chemical tools including signal perturbation methodology and high quality screening systems by applying the probe design strategies that we established. Likewise, we utilize our probe design principle to establish chemical tools for clinical use, including a tumor-specific intraoperative fluorescence imaging methodology. On top of that, we are now conducting dozens of pilot clinical trial projects by utilizing above mentioned chemical tools with external collaborators in domestic hospital and abroad.

The above-described areas of research have attracted enormous attention in recent years under the name of "Chemical Biology", and we believe that they will open up new horizons in life sciences.
Laboratory of Bioanalytical Chemistry

We measure the functions of biomolecules at the level of a single molecule to elucidate vital functions

Research Topics

1. Research on the principles of action by which biomolecular machines such as molecular chaperonin and ribosomes operate

2. Single-molecule fluorescence imaging of intracellular mRNA processing and transport

3. Development of micro nanodevices for analyzing the functions and interactions of biomolecules

In order to understand living organisms, it is necessary to conduct research at a variety of different levels. The lowest level is that at which biomolecules such as proteins and DNA work. When these come together, biological supramolecules, cells, organs, and the like are created, while at the higher end, individual organisms, societies, and ecosystems are constituted. We focus on the level of the smallest unit, the “biomolecule,” together with the level of the “cell,” at which life functions are first expressed, to find answers to questions like “By what mechanisms do biomolecules function?” and “When they aggregate, what kinds of systems do they construct?” Concretely speaking, we bind a fluorescent dye to a single biomolecule and observe it with a sensitive fluorescence microscope. Some biomolecules can exhibit their functions even at the level of the single molecule. For example, the motor protein known as kinesin moves on rail proteins called microtubules. Humankind does not at this point in time possess the technology for creating this kind of molecular machine, but we believe that humankind will be able to make this kind of molecular machine in the near future through research on the motor protein. On the other hand, self-assembly of a variety of different biomolecules creates complex systems which differ greatly from manmade ones. By researching such biological systems, we close in on the mysteries of life.

Fluorescence microscope system for imaging single molecules within living cells

The principle of single-molecule imaging of enzyme reaction (ATPase) using evanescent illumination
Laboratory of Physical Chemistry

We develop original NMR methods for elucidating protein functions based on dynamical structure information

**Research Topics**

1. Elucidation of the functional dynamics of membrane proteins
2. Reconstitution of membrane proteins into lipid bilayer condition with tailored stable isotope labeling for in situ NMR analyses.
3. Analyses of protein-protein interactions involving intracellular signaling
4. Development of new NMR methods for analyzing the structure and dynamics of high molecular weight proteins
5. Real-time observation of the intracellular biological events using the in-cell NMR method

Membrane proteins play fundamental roles in many biological processes, and are recognized as the principal target proteins for drug development. Recently, accumulating evidence has suggested that membrane proteins are structurally dynamic, and exist in an intrinsic conformational equilibrium, such as between the active and inactive conformations.

We use NMR for obtaining dynamic structural information about the membrane proteins under physiological conditions. We have analyzed the relationships between the dynamical structures and the functions for biologically important membrane proteins: GPCRs, ion channels, and adhesion molecules (Figure 2). To achieve this goal, we are developing new methodologies, including the reconstitution of membrane proteins within lipid bilayer conditions, a sophisticated stable isotope labeling techniques, and NMR methods for analyzing the structure and dynamics of high molecular weight proteins.

Figure 2: The functional dynamics of membrane proteins revealed in our group.
(A) The efficacy of GPCR ligands, (B) The gating mechanism of potassium channel (KcsA), (C) The cell rolling mechanism mediated by CD44
Determining three-dimensional structures of proteins and nucleic acids, and elucidating their functions in living cells

**Research Topics**

1. Structural analyses of proteins and nucleic acids using X-ray crystallography and small angle X-ray scattering
2. Structures of immune-system proteins and their complexes
3. Structures of proteins in signal transduction and their complexes
4. Single particle analysis by cryo-electron microscopy

Structural biology seeks to provide a complete and coherent picture of biological phenomena at the molecular and atomic level. The three-dimensional structure of macromolecules at an atomic level can create an actual picture of how they work. These days, structural biology is also called structural cell biology and/or structural life science, and is changing into the research field toward life science. Our laboratory aims at achieving a comprehensive understanding of structure/function relationships of key cellular components and processes, and roles in living cells. In the elucidation of three-dimensional structures, X-ray crystallography is extensively used since this method provides us with detailed structural information on the biological functions and roles. We also take an interdisciplinary approach, combined with methods of biophysics, biochemistry, molecular biology, genetic and protein engineering. Moreover, we take small angle-X-ray scattering (SAXS) and cryo-electron microscopy (cryo-EM). SAXS can provide a wealth of structural information on biomolecules in solution and is compatible with a wide range of experimental conditions. Cryo-EM has triggered a revolution in structural biology and has become a newly dominant discipline. Especially, single particle cryo-EM has become a powerful method for atomic structure determination. With these structural biological approaches, we can obtain the information on three dimensional structures that are required for drug design and discovery.

We are now carrying out structural biological researches into immune-system proteins, nuclear proteins and proteins in signal transduction.

Laboratory of Health Chemistry

Exploration of new functions for biomembranes and their constituent lipids

Research Topics

1. Molecular mechanism of lipid biosynthesis and homeostasis
2. Molecular mechanism of membrane dynamics (e.g., endo/exocytosis)
3. Identification of new bioactive lipids and elucidation of their functions

Biomembranes serve as barriers that segregate cells from the external environment. They also produce intracellular organelles, and are essential for cellular functions. The Laboratory of Health Chemistry aims to elucidate the physiological functions of lipids, essential constituents of biomembranes. Over 1,000 lipid species exist in biomembranes, and the appropriate balance among them is assumed to be fundamental to stability, activity, and localization of proteins, and regulation of gene expression. We focus on major components of cellular lipids, called phospholipids, and are trying to identify proteins involved in their biosynthesis and homeostasis. We also study the functions of lipids in the dynamic behavior of biomembranes, such as endo/exocytosis.

Various bioactive lipids are formed from membrane phospholipids, and affect a range of biological phenomena and diseases. Our study also focuses on “inflammatory response” which is the underlying condition of lifestyle-related diseases. To better understand the molecular mechanisms underlying inflammation, we are trying to comprehensively clarify when, where and how much lipid mediators are formed in the inflammatory sites using LC-ESI-MS/MS-based lipidomics system.
Mechanisms of cell division and their application to drug development

**Research Topics**

1. Mechanisms of centrosome duplication and its theoretical model
2. Mechanisms of cell division regulated by divergent molecular machineries
3. Identification and characterization of non-coding RNAs that regulate cell division
4. Comparative cancer cell biology and its application to anticancer drug development
5. Forward genetic analysis of cell-cell communication with human cells

Our laboratory mainly focuses on understanding the mechanisms of cell division, with a particular emphasis on the molecular basis and theoretical model of centrosome duplication. We are also interested in elucidating how divergent molecular machineries, including a protein complex and protein-lncRNA complex, regulate somatic and meiotic cell division. Based on these studies, we then explore a new approach to develop a novel anti-cancer therapy. To this end, we currently use the combination of innovative and multi-disciplinary methods including molecular biology, biochemistry, biophysics, structural biology, genetics, computer simulation and cell biology.

Furthermore, to understand molecular mechanisms and basic principles underlying a wider range of biological phenomena in vivo, we are also trying to establish a forward genetic approach with in vitro reconstitution of human cell-cell communication.

Laboratory of Molecular Biology

Molecular investigation of brain development, homeostasis and diseases

Research Topics

1. Investigation of the mechanisms responsible for the regulation of neural stem-progenitor cell fate during neocortical development
2. Investigation of genetic and epigenetic regulation of neuronal differentiation-maturation and activation-plasticity
3. Identification and characterization of the embryonic origin of adult neural stem cells
4. Dysregulation of neural stem-progenitor cell fate in neurodevelopmental disorders
5. Investigation of innate immune responses and their relation to brain development and disorders

The human body is composed of hundreds of different cell types that each perform distinct functions but which (except for the germline) all contain the same genetic information. A fundamental question with regard to tissue development is how tissue stem cells or multipotent progenitor cells give rise to various cell types in appropriate numbers and at the right locations to achieve tissue organization. Our laboratory has focused on identifying the mechanisms and logic that underlie the regulation of neural stem-progenitor cell fate both during embryonic brain development and in adulthood. We are currently investigating genetic and epigenetic regulation of neural stem-progenitor cell fate and neuronal maturation as well as the genesis and maintenance of adult neural stem cells. We are also studying the relevance of these processes to neurodevelopmental disorders.

The lab works on a variety of research topics, including the investigation of the mechanisms responsible for the regulation of neural stem-progenitor cell fate during neocortical development, the study of genetic and epigenetic regulation of neuronal differentiation, the identification and characterization of the embryonic origin of adult neural stem cells, dysregulation of neural stem-progenitor cell fate in neurodevelopmental disorders, and the investigation of innate immune responses and their relation to brain development and disorders.

Obtaining genetic and epigenetic regulation of neural stem-progenitor cell fate and neuronal maturation as well as the genesis and maintenance of adult neural stem cells is crucial. The lab's research is also focused on understanding the relevance of these processes to neurodevelopmental disorders.
Research of cell and tissue communications for establishment and maintenance of cell society

Research Topics

1. Regulation and function of cell death in development, growth, regeneration and aging
2. Regulation of cell number and size of tissue via programmed cell death mechanism
3. Roles of dying cells as a signal center
4. Metabolic regulation of tissue regeneration and aging
5. Nutritional and gut microbial regulation of organismal homeostasis

Programmed cell death functions in dynamic tissue formation or remodeling. We have revealed that in the embryonic development, or aging process, caspases are activated by physiological stresses and exert regulatory functions. We aim to reveal how cell society is constructed and maintained during development, growth, regeneration and aging process with a particular focus on understanding the regulatory mechanisms and functions of cell death. We believe that our research would stimulate and encourage students and researchers to have the breadth of vision for life science research and provide new insights into the molecular logic underlying the formation and maintenance of cell society.

Dying cells act as a signal center, thus actively influence neighboring cells and tissues. Cell death is an instructive biological phenomena for establishment of cell society.
Laboratory of Cell Signaling

From signal transduction to drug discovery

Research Topics

1. Signal transduction and functions of ASK family proteins
2. Exploration of novel signaling molecules involved in cell death and stress responses
3. Molecular mechanisms of pathogenesis induced by dysfunction of stress signaling

The Laboratory of Cell Signaling has been focusing on analyses of the intracellular signal transduction, through which we seek to elucidate molecular basis of human diseases and identify novel drug targets. Our current research mainly focuses on the pathophysiological roles of stress responsive signals in various diseases such as cancers, immune disorders, cardiovascular diseases and neurodegenerative diseases. In addition to molecular genetic tools such as mice, flies and worms as well as basic experimental techniques from molecular cloning to protein biochemistry, we always incorporate novel analytic technologies such as mass spectrometry-based proteomic analysis and genome-wide RNAi screening systems into our research exploring “target molecules and molecular mechanisms”. By taking advantage of such experimental approaches, we aim to open up new fields in pharmaceutical sciences with paying attention to whole body physiology, diseases and drug discovery.
Elucidating various biological phenomena controlled by proteolysis

Research Topics

1. The action mechanisms of the proteasome, a multisubunit macromolecular complex responsible for regulated protein degradation in eukaryotic cells
2. Proteasome dysfunction in human diseases (senescence, malignant tumors, inflammation, neurodegeneration)
3. The mechanism of maintenance of protein homeostasis by the ubiquitin-proteasome system
4. The mechanism of T-cell positive selection by the thymus-specific proteasome

The proteasome is a supramolecular proteolytic apparatus that exists in all eukaryotic cells. The proteasome plays pivotal roles in various cellular functions by selectively degrading ubiquitinated proteins. It is also central to the maintenance of protein homeostasis (proteostasis). In recent years, it has become evident that the impairment of proteostasis is a hallmark of senescence, and the decline of proteasome function is drawing attention as one of the primary factors. Indeed, it has been shown that age-associated diseases develop as proteasome function declines with age, and that artificial increase in proteasome activity prolongs the healthy lifespan in nematodes and Drosophila. However, in mammals, means to enhance proteasome function has not been found at present. This is because in mammals the proteasome is controlled more complicatedly and because the mechanisms by which the proteasome function decreases with aging and by which a decrease in proteasome function causes senescence are not understood. On the other hand, it has become clear that inhibition of proteasome function is an important therapeutic strategy in malignant tumors where proteasome hyperactivity is observed.

The ultimate goal of Laboratory of Protein Metabolism is to create a method of intervention in pathologies involving proteasome dysfunction. To this end, we are researching detailed mechanisms of action and regulation of the proteasome by using techniques such as molecular and cell biology, comprehensive gene screening, proteomics, and mouse genetics.
Laboratory of Immunology and Microbiology

Understanding the principles of immunological tolerance and homeostasis

Research Topics

1. Mechanisms of immunological tolerance and homeostasis
2. Mechanisms of regulatory T cell development and function
3. Mechanisms of memory CD8 T cell maintenance

The immune system has evolved the ability to distinguish “self” from “non-self” to maintain homeostasis of the body. The immunological “self” is established in an adaptive and acquired manner through continuous interactions with changing internal as well as external environments. The ultimate goal of this laboratory is to elucidate, throughout multiple layers, from molecules, cells, cell populations, tissues, to individuals, the principles that govern the development of such immunological “self” and its transformation during diseases. Towards this end, we focus on a cell-extrinsic, dominant control mechanism of the immune system that depends on a subpopulation of T lymphocytes called regulatory T (Treg) cells. As one approach, we elucidate how mutations in the Foxp3 gene, encoding a transcription factor critical for Treg cell development and function, lead to a breakdown of immunological tolerance and homeostasis.

Fig. 1: Disintegration of immunological “self” underlies a variety of diseases

Fig. 2: Foxp3-expressing regulatory T (Treg) cells are indispensable for immunological tolerance and homeostasis

Elucidation of the mechanisms determining pharmacokinetic properties of drugs that contributes to drug design, and safe and effective utilization of drugs

Research Topics

1. Establishment of the methodologies for in vitro-in vivo extrapolation of drug pharmacokinetics and pharmacological effect
2. Elucidation of molecular mechanisms determining the intestinal absorption of drugs, clearance of drugs from liver/kidney and drug transport at the barrier organs such as blood-brain barrier
3. Prediction of the effect of genetic polymorphisms of metabolic enzymes/transporters on the inter-individual variations of drug pharmacokinetics
4. Establishment of the methodologies for the quantitative prediction of drug-drug interaction risks
5. Elucidation of mechanisms for the membrane trafficking of transporters
6. Development of transporter-based drug delivery system (DDS)
7. Elucidation of mechanisms of drug-induced toxicity

Pharmacological and adverse effects of drugs depend on their pharmacokinetic properties, which determine their exposure to the targets. Our laboratory aims to establish methods for quantitative and theoretical prediction of pharmacokinetic properties of new chemical entities in humans based on the molecular mechanisms. In particular, we investigate the impact of transporters on the elimination of drugs from the liver and kidney, the distribution of drugs into their target organs e.g., the brain, and drug absorption in the small intestine, in order to develop drug screening systems and to elucidate the mechanisms of drug-drug interaction, and interindividual variation in pharmacokinetics of drugs. We have also started research on the regulation of membrane trafficking of the transporters using low molecular weight compounds to cure transporter related-diseases. Research achievements in this laboratory contribute to predicting and evaluating rational pharmacokinetic properties in drug development, drug review and regulation, and in clinical use, and to developing medical therapy for transporter related-diseases.

An example of a drug successfully designed to minimize interindividual variation in pharmacokinetics by considering transporter characteristics.

As a high-throughput screening system for hepatobiliary transport, uptake and efflux transporters are simultaneously expressed in a single polarized cell (double transfectant).
Pharmacological approach toward the brain: from molecule to animal

Research Topics

1. Exploring a new dimension of brain function via Brain-AI hybrid
2. Studying brain network operation using multicellular activity recording
3. Studying neuronal network formation during development

Pharmacology includes two aspects: 1) to analyze the biological action of drugs and 2) to search the strategies for developing treatments for diseases. We conduct our pharmacological research by taking advantage of state-of-the-art technologies and a wide range of knowledge from molecule to animal. We focus on the roles of the cerebral limbic system and cerebral cortex, in particular, the hippocampus and amygdala, which are involved in learning, memory, and emotion.

Our experimental techniques cover from genetics, biochemistry, and cell biology to electrophysiology, histochemistry, and behavioral pharmacology. Recent technical advances have allowed us to investigate the neuronal network dynamics on far larger scales than hitherto. Functional multineuron calcium imaging reveals the dynamics of network activity with single cell/synapse resolution (Upper Figure), through which we elucidate the structural and functional relationship that generates spatiotemporally organized spike patterns. We also address the mechanisms of learning and memory using in situ mapping learning-relevant neuronal circuits with immediate early genes with cellular and temporal resolution (Lower Figure).

We believe that these novel approaches open up a new avenue for our mesoscopic understandings of network function and malfunction associated with depression, stress-relevant disease, and epilepsy.
From understanding the molecular pathogenesis of neurodegenerative and psychiatric diseases to development of therapeutics and novel basic science

Research Topics

1. Research on Aβ metabolism (production, secretion and clearance) and its regulatory mechanisms
2. Understanding the cellular pathology after Aβ deposition towards the development of diagnostics
3. Elucidation of mechanism of amyloid formation deposited in the brains of patients
4. Investigation of the pathological function of microglia in Alzheimer disease
5. Understanding the molecular pathomechanisms of Parkinson disease
6. Elucidation of molecular mechanism of propagation of α-synuclein pathology
7. Biological and pathological roles of synaptic adhesion molecules in psychiatric disorders
8. Development of exercise program for dementia prevention

Aim of our laboratory is that understanding the molecular pathogenesis of neurodegenerative and psychiatric diseases to develop novel approaches to therapeutic, prevention and diagnosis. Also, we are pursuing novel basic science by understanding the molecular basis of diseases. Especially, we are studying Alzheimer disease, autism spectrum disorder and schizophrenia to identify the pathological mechanisms and therapeutic targets of these diseases at molecular levels. To understand the disease condition, we have to realize the basic mechanisms of cells and living organisms, and vice versa. We believe that this disorder-to-normal cycle in research is a basis of modern disease and basic biology, and bolsters both scientific areas by novel knowledge and technology. From this standpoint, we proceed disease-oriented molecular and cellular research in a multidisciplinary manner by mutual collaborations with organic chemists, structural biologists, physicians and pharmaceutical companies.
Laboratory of Pharmaceutical Regulatory Science

Establishing scientific drug evaluation

Research Topics

1. Advancing methods for rational drug evaluation
2. Analyzing drug development behaviors and policies
3. Evaluating drug regulation and guidelines
4. Developing systems to implement the above policies and guidelines

The goal of our research is to establish scientific principles and methods in drug evaluation with societal perspectives in mind. Pharmaceutical research and development (R&D), clinical development in particular, regulatory review and approval of new drugs, and post marketing activities are our research interests. We provide evidence on R&D efficiency, performance and outcomes of regulations, and public health impact through rigorous analysis based on economic models. Conflicts in global pharmaceutical R&D, including recent launch delay of new drugs in Japan and so-called ethnic differences, are always high on our agenda. Aside from the research activities, we also make efforts to develop human resources in both private and public sectors with up-to-date knowledge, ethics, and philosophy, and rationale in drug evaluation. We offer lectures for graduate and undergraduate students, and a half-year training course for industry and regulatory professionals. We aim to secure transparency and social responsibility on drug regulation through our research and educational programs.

Toki, T., Ono, S. Spontaneous reporting on adverse events by consumers in the United States. Drugs-Real World Outcomes DOI:10.1007/s40801-018-0134-0 (2018)

An overall analysis is made of the old-yet-new drugs known as “medicinal plants” (crude drugs) to develop new ways of using them (utilizing the resources in the Experimental Station for Medicinal Plant Studies)

Research Topics

1. The cultivation of medicinal plants and tissue cultures
2. The production of useful secondary metabolites, using plant tissue culture technology
3. Chemistry and biosynthesis of plant-derived biologically active substances

Since prehistoric times, plants have been the principal material used as drugs by humankind. Many have fallen by the wayside through a long process of trial and error (human experiments), and the ones that remain can be considered the crude drugs of the present day. In recent years, the percentage of all drugs accounted for by antibiotics and biologics has increased, but the importance of plant-derived pharmaceuticals is by no means diminished and has led to the discovery of new drugs such as Taxol and vinblastine. Thus, the study of medicinal plants is by no means completed, and is continuing to evolve.

The Experimental Station for Medicinal Plant Studies, formally established in 1973, is located adjacent to the Kemigawa Athletic Ground. The saplings transplanted there back then have grown large and now form a dense enclosure of trees around the garden.

At the research lab in Hongo, we conduct research on the production of useful secondary metabolites using plant tissue culture technologies (from the induction of culture cells to the production of substances). Some of the research topics we are currently pursuing are the biosynthesis of diterpene constituents from Gymnosperm plant cultured cells, the production and biosynthesis of diterpene alkaloids using cultured tissue of monkshood, the production and biosynthesis of phenylethanoids using cultured cells of olive, and the production of biologically active constituents of Egyptian medicinal plants by means of plant tissue culture technologies.

Laboratory of 
Applied Immunology 
(IQB Laboratory of Immunology and Infection Control)

Research on immunoglobulin diversification and gut microbial regulation by intestinal IgA

**Research Topics**

1. Mechanism of gut microbial regulation by intestinal IgA
2. Molecular mechanism of somatic hypermutation of immunoglobulin genes
3. Search for IgA class switch inducer

The immune response has evolved to protect us from pathogenic infectious agents and toxic foreign substances. In acquired immune response, antigen stimulation of B cells induces two distinct genetic alterations in the immunoglobulin (Ig) loci: somatic hypermutation (SHM) and class switch recombination (CSR), both of which require an enzyme, activation-induced cytidine deaminase (AID). After these processes, among diversified Ig repertoire, selected high-affinity Igs efficiently defend host. AID plays a crucial role in host defense but it introduces DNA cleavage into Ig loci and aberrantly into non-Ig loci causing lymphoma. Our aim is to answer “how AID’s activity targets Ig loci specifically” using AID mutant protein and mutant knock-in mice and to understand the precise molecular mechanism of SHM and CSR.

Recently dysbiosis (gut commensal microbial imbalance) is frequently reported to be associated with illnesses such as inflammatory bowel disease (IBD), obesity, cancer, etc. We found that the high-affinity intestinal IgA produced by SHM is important to control non-pathogenic gut bacteria as well as pathogens. Our main question is how intestinal IgA recognizes and targets a huge variety of gut bacteria. We have isolated a useful monoclonal IgA to modulate gut microbiota leading to symbiosis (balanced host-microbial relationship in gut). We aim at applying the findings of our basic research to practical medicine.

Major Research Topics

1. Mechanism of gut microbial regulation by intestinal IgA
   We generated hybridomas from IgA producing cells in small intestine of wild type mice. We selected W27 monoclonal IgA as a best gut microbial modulator because of its strong binding ability specifically against colitogenic bacteria. We are analyzing the bacterial target molecule for W27 to control microbial community, and will elucidate the reason why IgA selects that target in the point of physiological view. We aim at the development of therapeutic W27 IgA antibody.

2. Molecular mechanism of SHM
   We have found that a N-terminal mutant AID (G23S; glycine to serine mutation at the 23rd AA) showed defective SHM but relatively intact CSR both in vitro and in vivo, suggesting the N-terminus of AID may be the domain responsible for SHM-specific co-factor binding. Through the search of SHM-specific co-factor, we will understand how AID distinguishes SHM from CSR.

3. Search for IgA CSR inducer
   Upon antigen stimulation B cells can undergo CSR to IgG, IgE or IgA isotype. However, what induces B cells to each isotype specifically is not completely understood. We focus on searching a novel IgA CSR inducer, which may drive IgA CSR instead of IgE CSR at mucosal surface, helping prevent allergy, as well as enhance the mucosal immunity.

Investigation of chromatin dynamics in germ cells

**Research Topics**

1. Profiling sperm-retained histones
2. Elucidating the sperm chromatin structure
3. Investigation of the mechanism of histone retention in sperm during histone-protamine exchange

“Neuronal cells are who you are, while germ cells are where you came from.” — This is the word by a leading scientist in the field of germ cell research. Somatic cells including neuronal cells compose ourselves, while germ cells play transgenerational roles. Recently, scientists demonstrated that not only DNAs but also certain non-DNA factors can be transgenerationally transferred from ancestors to progenies. The substance of this is non-DNA material is supposed to “epigenome” such as chromatin and small RNAs, although the real entity hasn’t been determined. For now, the most possible idea is that the parental epigenetic information in their germ cells is altered upon stress responses and transferred to the progeny by fertilization.

In our laboratory, we are investigating how epigenetic information is established in germ cells (especially in male germ cells) and altered upon various stress responses using biochemical, molecular biological, and genomic approaches. In addition, we are trying to utilize our research outcome for sperm quality control in Assisted Reproductive Technologies (ART).

An example of our research achievement. Mammalian sperm nuclei are tightly condensed due to the highly basic proteins called protamines. This unique chromatin structure prevents us from performing various kinds of biochemical approaches to investigate the characteristics of sperm chromatin. In order to overcome this problem, we developed a new method to artificially remove protamines from sperm chromatin by treating them with nucleoplasm (left figure). This treatment enabled us to extract histone-DNA complex from sperm chromatin, then we performed Chromatin Immunoprecipitation-Sequencing (ChIP-seq) to determine where histones are retained in sperm genome. The result tells us that histones are scattered across the genome and exhibit modest enrichment in repeat regions. Interestingly, post-translationally modified histones are retained in specific genome elements depending on the patterns of their modifications (right figure). Recently, paternal lifestyle and habits are supposed to be transferred to their children through sperm. This phenomenon is called “epigenetic inheritance”, and our research outcome is expected to provide a useful knowledge for understanding its molecular mechanisms.
Laboratory of

Cellular and Molecular Chemistry

(Division of Stem Cell and Molecular Medicine, The Institute of Medical Science)

Elucidating various life phenomena through stem cell research

Research Topics

1. Molecular mechanism of stem cell self-renewal
2. Epigenetics of stem cell aging
3. Epigenetics of cancer

Stem cells have the remarkable capacity to both self-renew and give rise to many types of more specialized cells in the body, which explains their great therapeutic potential in regenerative medicine. But that’s not the only reason stem cells have become such a hotbed of scientific inquiry. These cellular transformers also offer an invaluable research tool for probing the disease mechanisms that underpin cancer, aging and a host of other health problems. Our major interest is to elucidate the mechanisms of self-renewal and multi-lineage differentiation of hematopoietic stem cells (HSCs). We are also interested in how the deregulated HSC functions are associated with aging of our body and the development of age-related hematological malignancies. We approach these issues mainly from the viewpoint of epigenetics, such as DNA and histone modifications and higher order chromatin architecture.
Laboratory of
Clinical Pharmacokinetcs
(The University of Tokyo Hospital)

Systems-pharmacological studies for drug development in the next-generation

Research Topics
1. Therapies for lifestyle-related diseases based on the comprehensive understanding of molecular mechanisms that control the transport of endogenous small molecules
2. Therapies for bone metabolism diseases based on the comprehensive understanding of the dynamic control mechanisms of signal molecules involved in bone resorption and formation
3. Quantitative understanding of the pharmacological and toxicological effects of molecular targeted anti-cancer drugs to establish clinical applications and new drug discovery techniques
4. Large-scale omics analysis to establish methods of preventing and treating adverse drug reactions based on the quantitative understanding of underlying molecular mechanisms
5. Clinical pharmacokinetics based on detailed quantification of related molecular functions

It has been recognized very well that we need to describe / predict the functions of cells, tissues and organisms from the function of each constituent molecule in a quantitative manner in order to understand the life activities. Although we have used such approach in analyzing and predicting the drug disposition in humans, it is quite important for us to expand the concept to the analysis of pharmacological / toxicological actions of drugs in humans. We are using such “systems-pharmacological” methods to solve many kinds of problems that remain great challenges in drug discovery, such as how to identify the most effective target molecules among numerous candidates, and how to comprehensively predict the adverse drug reactions in humans.
Endowed Laboratory of
Drug Lifetime Management

Drug lifetime management for development of excellent drugs, proper use of drugs, and evolution of drugs

Research Topics

1. Development and practice of methodologies for the collection, evaluation, analysis, and distribution of drug post-marketing information
2. Creation of programs for promoting proper use and evolution of drugs in community healthcare
3. Development of new features in the community pharmacy to practice the above-mentioned 2
4. Specification, standardization, and digitization of drug information, and their clinical applications
5. Quantitative prediction of the effects of biodisturbance factors on pharmacokinetics and drug effects

Our university’s Faculty of Pharmaceutical Sciences bears the social mission of promoting drug discovery and the proper use and evolution of drugs while improving the quality of drug therapies. To these ends, this course in Drug lifetime management pursues various research to ensure that the developed drugs can amply exhibit their effects and lead a substantial “drug life.”

The research topics of this course are that (1) the proper collection of drug information (DI), (2) evaluation/analysis of DI based on pharmacokinetics and pharmacodynamics and quantitative prediction of changes in pharmacokinetics and drug effect due to various risk factors, (3) Qualitative evaluation and analysis of the individual cases, (4) Creation of archive based on the optimal specification/standardization/digitization of DI, and (5) their proper provision to the clinical field. Concretely speaking, the content of our research is to seize drug post-marketing problems (including trouble and needs related with drugs), to make a proposal, to the pharmaceutical field, for evolving drugs and their information in order to solve the problems, and to feedback them to the clinical field.

The central dogma of pharmaceutical development consists of the cycle of drug discovery → proper use of drugs → post-marketing drug development → drug discovery and so on

Collection of drug post-marketing information with appropriate method (from whom? from where? How?).
Maximizing and evaluating true "value" of various medical interventions, not only its impact for health care budgets but for health outcomes, to maintain and improve public health care system.

**Research Topics**

1. Health Technology Assessment (HTA)
2. Health economic analyses for drugs / medical devises
3. Surveys on public healthcare system / reimbursement system
4. Research on QOL (Quality of Life) instruments

There are growing concern about the cost issue of medical care interventions, as the sustainability of universal health coverage system is threatened with the increase of health care budget, in particular with introduction of expensive medications, such as drugs for cancer, hepatitis or life style diseases. Many stakeholders in Japan, not only health economists but also physicians, governmental decision makers, and industry officers have keen interest on health economics and outcomes research (HEOR), including QOL survey.

Efficiency data, or cost-effectiveness data, would play more role in decision making process, as well as efficacy and safety data would do.

We define the word “HEOR” with broader definition; any kind of researches which can maximize/quantify the value of particular medical interventions and/or disease area. Then, our research topics would range from narrower ones, like cost-effectiveness analyses of particular products to broader ones, like conceptual research for QOLs and the analytical methods.
Endowed Laboratory of
Human Cell-based Drug Discovery

Establishment of efficacy and safety models for drug discovery using human iPS-derived cells, such as neurons, cardiomyocytes, hepatocytes, etc.

Research Topics

1. Studies on developing new translational assay systems for clinical drug efficacy and safety with human iPS-derived cells, culture systems and devices
2. Establishment of test methods to predict adverse effects of medicines on CNS and cardiac function
3. Physiological and pharmacological studies to predict and prevent adverse drug reactions on learning and memory using human iPS-derived neurons and astrocytes, and imaging technologies
4. Development of morphological image analysis frameworks for cell structure images using artificial intelligence
5. Educational activity of knowledge, technology and application of iPS cells

The recent problem of low success rate in drug discovery is a big issue that we should solve for human health. Technology of induced pluripotent stem cells (iPSC) is expected to offer solutions for the problem. The low success rate is due to uncertainty for efficacy and safety in clinical trials. Unpredictable adverse effects usually come from limitation of the predictability of preclinical tests using the laboratory animals. Usage of a human cell-based tool for preclinical tests will overcome the limitation of animal experiments. Our laboratory is focusing on establishment of new translational assay systems for efficacy and safety with human iPS derived cells, new culture systems and newly developed devices. We have recently validated a new safety pharmacological method with electrophysiological using cardiomyocyte derived from human iPSC. We are seeking more precious methods for cardiac safety of anti-cancer drugs. We are developing immunocytochemical assay for drugs acting on synaptic function and structure. There will be many applications for drug discovery using human iPSC derived cells; clinical tests in a dish at the stage of preclinical test, establishment of disease models and precision medicines.

We are organizing the tripartite research team with donation companies. Our laboratory will be a hub of the network of the academia, industries and regulators.

A. Human Cell-based Drug Discovery

B. Network Architecture

We are developing translational assay systems for drug efficacy and safety with human iPS derived cells, new culture systems and new devices.

We are organizing the tripartite research team which will be a hub of academia, industries and regulators.
Social Cooperation Program of Brain and Neurological Disorders

Drug discovery research for development of innovative therapies against brain and neurological disorders

Research Topics

1. Understanding the role of intracellular trafficking in the pathogenesis of neurological disorders
2. Drug discovery research for accelerating the clearance of aggregated proteins in the brain
3. Development of innovative therapies for recovery of damaged neuronal circuits

We are facing super-aging society, and developments of diagnostics, prevention and therapeutics against brain and neurological disorders (e.g., dementia) have been required. However, to date, only a limited number of drugs for these diseases has been available. Our laboratory aims to understand the pathogenesis of brain and neurological disorders and identify key molecules that lead to development of prevention and therapeutics. At the same time, we seek biomarker molecules for early and specific diagnosis of the disorders. Our laboratory also conducts mutual collaborative researches between academia, industry and students. We believe that such collaborative approaches will lead to development of innovative therapies against these neurological diseases and help to establish the healthy super-aging society with multi-generational relationships. Also, advanced research experiences in our laboratory would cultivate next generation researchers for drug discovery.

We aim to develop a simplified assessment system for chemical safety using human-derived cell lines.

**Research Topics**

1. Development of chemical toxicity (cardiotoxicity and hepatotoxicity) prediction methods for gasses using human-derived cell lines.

We are daily exposed to various chemical compounds such as drugs, cosmetics and food additives. To make our lives more comfortable, chemical manufacturers are trying to develop new novel chemical substances that pass the safety assessment processes. During the processes, animal toxicity testing has been employed to date. However, it takes a large amount of time and costs a lot of money to obtain results, which is a heavy burden for companies.

In order to develop new chemical substances more quickly, it would be desirable to establish an assessment system at a low cost and in a short period of time. In addition, based on the principles of the 3Rs (Replacement, Reduction, and Refinement), which refers to the ethical use of animals in testing, alternative methods without using animals such as toxicity prediction using structure-activity relationships and toxicity testing using mammalian cells, are in great demand.

Considering the current situation, we will focus on gaseous substances and try to establish a toxicity assessment system using human-derived cell lines. We will also be engaged in normalization of the methods to make our knowledge as beneficial as possible.
Social Cooperation Program of IT Healthcare

Research on innovation in drug development and proper use through ICT utilization

Research Topics

1. To realize paradigm-shift in clinical data collection & generation
   From site-bound to patient-based clinical trial (site-less, remote-, virtual)

2. To realize paradigm-shift in post-marketing activities
   Adopting ICT to pharmacist service to realize effective disease management & prevention

3. To realize patient centered medicines development
   Introducing global educational program and adaptation to local practice.
   Proposing better support for patients (and their associations)

4. To realize disease epidemiology research and medical innovation through exploratory analysis of real world data (RWD)

The IT Healthcare Social Cooperation Program was opened on November 1, 2018 at the University of Tokyo’s Graduate School of Pharmaceutical Sciences as a joint research course with universities and companies, aiming to develop pharmaceuticals centered on patients by introducing innovative technologies and networking into the collection of clinical outcome data, a major issue in clinical development. We will also conduct research necessary to foster the professionalism of pharmacists who contribute to patient-centered medication management and instruction with the aim of realizing scientific and ethical health promotion.
Laboratory of
Fluorescence Chemical Medicine

Creation of novel clinical technologies for fluorescence medicine on the basis of new technologies and concepts of organic chemistry

Research Topics

1. Establishing an efficient method to find out novel fluorescent probes which provide a solution for clinical needs
2. Development of fluorescence detection method and related technologies applicable to clinical diagnosis
3. Basic research required to solve the problems described above, including optimization of fluorescent probes

According to recent statistics, one in two Japanese people will have cancer in their lifetime. Hence, development of more accurate, easier to perform, and less expensive detection method of tumors during surgery is important. In addition, more precise diagnostic technologies for neurological diseases and infectious diseases are also significant. To address the social needs, we apply fluorescent activatable probe technologies based on organic chemistry, to provide a solution to the problems. In particular, we will develop effective strategies for screening clinically useful probes, and also perform actual screening to create “fluorescent navigation drugs”. Further, we will try to overcome difficulties which hinder the applications of the probes to actual clinical diagnosis, and optimize the properties of the probe, when needed. In the course of the research and the development, it might be required to solve various problems by collaborating with clinical researchers and cooperate researchers. Through such practices, we educate human resources who can explore the novel field of “Fluorescence Chemical Medicine”.

Research and development for the implementation of fluorescence chemical medicine

Fluorescent detection of breast cancer using gGlu-HMRG

Clinical research data using breast cancer surgery specimens. The probe reacted with an enzyme overexpressed in the breast cancer tissue and strongly fluoresced.
In 1869, Meiji government decided to adopt German medicine and asked the minister of the North German Federation to send 2 instructors. In 1871, Müller (chief Army physician/staff surgeon) and Hoffman (Navy physician/staff internist) arrived in Japan and assumed their duties at the University East Building (Tôkô) in Shitaya Izumibashi (precursor of the Faculty of Medicine, University of Tokyo).

Müller and Hoffman, who were under the direct supervision of the Meiji Minister of Education, had absolute authority over medical education in Japan. A new curriculum was established with 3 preparatory years (changed to 2 the following year) and a 5-year main program.

Müller and Hoffman regarded “pharmaceutical sciences” as an independent branch of the natural sciences that was closely related to medicine, and they proposed the establishment of a pharmaceutical institute. This took shape in 1873 as the Department of Pharmaceutical Manufacturing, established in The First University District Medical School. Müller returned to Germany in 1875. In October of 1895, upon the third anniversary of his death, a bust of Müller was erected to honor him as a benefactor of Japanese medicine and pharmaceutical sciences.

Dr. Shimoyama was born in Owari Inuyama in 1853. In 1873, after transferring to the Department of Pharmaceutical Manufacturing, The First University District Medical School (the precursor of the Faculty of Pharmaceutical Sciences, University of Tokyo), he graduated in 1878. He gave the “address in reply” at the first degree-conferring ceremony held by the Faculty of Medicine. In 1886, Dr. Shimoyama received the Doktor der Philosophie degree from Strasburg University in Germany and in 1899, he became the first person in Japan to be awarded a Doctor of Pharmaceutical Sciences degree.

Dr. Shimoyama became a professor of the Department of Pharmacy in the Faculty of Medicine in 1887, and a professor of a laboratory of Pharmacognosy, the Department of Pharmacy in 1893. While devoting great efforts to education and research, he also helped to cultivate successors through the establishment of the Pharmaceutical Society of Tokyo (the present Pharmaceutical Society of Japan) and the creation of a privately funded medicinal herb garden (Zekô Yakuen), etc.

Dr. Shimoyama died suddenly in February of 1912 while still in service as an educator. In remembrance of him, a bronze statue was erected beside the Pharmaceutical Sciences Building in 1913.

---

**Education Center for Clinical Pharmacy**

The center has been established in June, 2012. The purpose of the establishment is to enhance the educational research structure in those new educational programs, especially 6-year undergraduate program (Department of Pharmacy) and 4-year doctoral program (Department of Pharmacy).

**Research Topics**

1. Development of educational program for practice for clinical pharmacy
2. Development of educational program of clinical pharmacy
3. Development of postgraduate educational program for training leading pharmacists

---

**Dr. Leopold Müller**

In 1869, Meiji government decided to adopt German medicine and asked the minister of the North German Federation to send 2 instructors. In 1871, Müller (chief Army physician/staff surgeon) and Hoffman (Navy physician/staff internist) arrived in Japan and assumed their duties at the University East Building (Tôkô) in Shitaya Izumibashi (precursor of the Faculty of Medicine, University of Tokyo).

Müller and Hoffman, who were under the direct supervision of the Meiji Minister of Education, had absolute authority over medical education in Japan. A new curriculum was established with 3 preparatory years (changed to 2 the following year) and a 5-year main program. Müller and Hoffman regarded “pharmaceutical sciences” as an independent branch of the natural sciences that was closely related to medicine, and they proposed the establishment of a pharmaceutical institute. This took shape in 1873 as the Department of Pharmaceutical Manufacturing, established in The First University District Medical School. Müller returned to Germany in 1875. In October of 1895, upon the third anniversary of his death, a bust of Müller was erected to honor him as a benefactor of Japanese medicine and pharmaceutical sciences.

**Dr. Junichiro Shimoyama**

Dr. Shimoyama was born in Owari Inuyama in 1853. In 1873, after transferring to the Department of Pharmaceutical Manufacturing, The First University District Medical School (the precursor of the Faculty of Pharmaceutical Sciences, University of Tokyo), he graduated in 1878. He gave the “address in reply” at the first degree-conferring ceremony held by the Faculty of Medicine.

In 1886, Dr. Shimoyama received the Doktor der Philosophie degree from Strasburg University in Germany and in 1899, he became the first person in Japan to be awarded a Doctor of Pharmaceutical Sciences degree.

Dr. Shimoyama became a professor of the Department of Pharmacy in the Faculty of Medicine in 1887, and a professor of a laboratory of Pharmacognosy, the Department of Pharmacy in 1893. While devoting great efforts to education and research, he also helped to cultivate successors through the establishment of the Pharmaceutical Society of Tokyo (the present Pharmaceutical Society of Japan) and the creation of a privately funded medicinal herb garden (Zekô Yakuen), etc.

Dr. Shimoyama died suddenly in February of 1912 while still in service as an educator. In remembrance of him, a bronze statue was erected beside the Pharmaceutical Sciences Building in 1913.
Graduates of Faculty of Pharmaceutical Sciences, who have acquired a comprehensive fundamental understanding and applied knowledge of the field, receive extremely high respect, resulting in relative easiness to find a job. Over 90 percent of graduates choose to move forward to Graduate School of Pharmaceutical Sciences, the University of Tokyo. An increasing number of applications from the University of Tokyo, other universities, and foreign universities take an annual entrance exam in August. We have seen more and more of a social trend that prefers an individual with a researcher background and research experience higher than a Master's level. Our graduates who completed either undergraduate or graduate courses find positions in a wide array of fields, such as pharmaceuticals, chemical, and food related companies, universities, as well as government agencies.

Half of graduate students opt for the doctoral course. After acquiring a PhD., they find vast opportunities not only in the academic field, such as universities and public research agencies, but in researching departments of companies, as leaders of projects.
Undergraduate

There are roughly 80 students in each grade at the Faculty of Pharmaceutical Sciences, and this is one of the smallest faculties at the University of Tokyo. New students form close friendships in no time after starting their first year. They attend lectures and engage in pharmaceutical training, all the while maintaining close relationships with faculty members. Lectures encompass a broad range of academic fields closely related to real life medicine. Assistant professors and graduate students as teaching assistants also take part in the pharmaceutical training classes.

Second-year students begin to attend lectures on specialized topics for three days at the Hongo campus in the fall after receiving liberal arts education at the Komaba campus.

In the third year, students sit in on lectures in the morning and engage in pharmaceutical training in the afternoon. Lectures become more specialized, and during training sessions students work in groups of two to four.

Fourth-year students work in the laboratory of their choice, and they begin to focus less on classes and more on their senior research project.

Students must choose either the four-year program of the Department of Pharmaceutical Sciences or the six-year program of the Department of Pharmacy in their fourth year. Students who choose the Department of Pharmaceutical Sciences must complete a year-long senior research project in order to complete their degree. Those who decide on the Department of Pharmacy begin to work in the laboratory while they receive laboratory training for clinical pharmacy. At the end of the fourth year, students are expected to go through the Pharmaceutical Common Achievement Tests for clinical pharmacy. In the fifth year, students receive training for clinical pharmacy, and work in their laboratories. In the sixth year, students dedicate their time to working on their senior research project until graduation.

Postgraduate

Each laboratory and related laboratories (Institutes) of the Graduate School of Pharmaceutical Sciences and the Department of Pharmacy of the University of Tokyo Hospital conducts leading research in their specialized areas of focus. Students at the start of their graduate studies begin their research career by attending seminars and conducting experiments in world-renowned laboratories which are equipped with state-of-the-art facilities.

Campus Social Events

All the members form close-knit friendships, and this is not just because it is a relatively small department. The department hosts a slew of social events that include but are not limited to sports events, and activities with international students and researchers. These events contribute to the growth of friendships and close bonds outside of academic life. The close bonds of the students and researchers in this department foster collaboration, and this leads to a wider spectrum of academic insights and new developments in research.
With the dream of doing cosmetic research in Japan, I decided to take a master’s degree in Japan after graduating from Beijing University of Chemical Technology. Fortunately, with the acceptance of Pro. Funatsu, I won the opportunity to join the Laboratory of Bioanalytical Chemistry.

In the first year, as a research student, I started my research while preparing for the entrance exam of the Graduate School of Pharmaceutical Sciences. At first, I was a little uneasy because of the different major and new language environments. However, with the kind help from members of my laboratory, I quickly adapt to life at the University of Tokyo.

In the second year, I passed the entrance exam successfully and became a master student. During my master’s degree, I did two research projects, but one of the projects did not go well at first. Even so, my mentors and seniors continued giving me useful guidance, which encouraged me a lot. Then we started to collaborate with the Laboratory of Advanced Elements Chemistry and Ajinomoto. Finally, we completed the research successfully. Though the research experience, I began to realize the importance of cooperation because it allows us to analyze problems from multiple perspectives and find solutions more effectively.

In addition to laboratory life, I had many unforgettable experiences at the University of Tokyo. ISAR organized a variety of activities, such as international student trips, dumpling parties, and various Japanese cultural experience activities, which enabled me to enhance communication and understand different cultures. Also, ISAR provided Japanese classes and helped me to apply for a dormitory and scholarship. I appreciate all members of ISAR, especially, my Japanese teacher Ezure-sensei. She not only taught me Japanese but also gave me much good advice on my life and career plan. Thanks to these supports, I was able to complete my studies and found my ideal job.

After graduation, I entered a cosmetics company as I wish. My main job is to develop new skincare products. I have been working for two years and a half. However, I still miss lovely people, beautiful campus, and delicious Akamon Ramen of the University of Tokyo. I hope you can come here to pursue your dreams, and I believe this university can help you to make your dream come true!
In March of 2011, Japan was hit by a major earthquake, followed by a devastating tsunami and nuclear power plant leakage. It was not over a month after this catastrophe that I first flew to Tokyo to pursue an MS degree. Tokyo was the first city I ever lived in away from the comfort of home, family, and friends. Besides the initial safety concerns, there were many other adversities that had to be faced: my whole new life in a foreign land as an independent adult, adapting to a different culture and learning the local language, and as a graduate student, struggling to pursue a career in research. Many of my doubts and worries were resolved through communication with and support of the staff at ISAR. Not only so, ISAR provides free one-on-one Japanese language classes that, for me, were not only helpful in understanding Nihongo, but were also an emotional outlet and source of enjoyment and support. ISAR also organized many activities for international students, most memorable of which were the yearly outing to sight-see places around Tokyo and visit pharmaceutical companies, watching sumo wrestling, the sumptuous dinner on yakatabune, and the dumpling-making events, among others. The teachers and advisers at ISAR also helped me prepare for my interview to obtain scholarship support for my PhD studies. There are just too many fond memories to recall during the short 5-and-a-half years that I was in Japan, most of which are thanks to ISAR and the friends I’ve made in the Graduate School of Pharmaceutical Sciences.

Right after finishing my PhD, I went to the University of Connecticut to do postdoctoral research work, still in the field of natural products chemistry. Then, recently, I have just started my second stint as a postdoc in the field of asymmetric catalysis at a new research university in China, called the Westlake University. Although it is an entirely different research realm and yet another foreign country for me, I am confident that my experiences in Japan and the earnest work attitude and learning spirit instilled in me during my graduate studies at the University of Tokyo will continue to guide me in becoming my ideal researcher – one that values, and is of significance to, the society and humanity.

On a lighter note, the University of Tokyo was also where I first met my husband, and now, we have a little boy. Whereas I came to Tokyo alone, it gifted me with my most precious family, and my heart has never felt more complete!
The International Student Advising Room (ISAR), established in 1994, provides a variety of services to support international students and researchers. http://www.f.u-tokyo.ac.jp/~israr/en/isar/index.html

ISAR offers:
• Advisory assistance and a counseling service
• Information for prospective international students
• Event planning
• Inter-university academic exchange program
• Information services

• Japanese Language Class
The Japanese Language Class provides an opportunity to learn Japanese language to international students, researchers and their spouses. It also deals with a broad range of topics on Japanese society, culture, history, etc. There are a variety of courses offered from elementary to advanced level.

Experimental Station for Medicinal Plant Studies

Hanamigawa-ku, Chiba-shi, Chiba

The Experimental Station for Medicinal Plant Studies is located about 30 km east of the Hongo Campus. Its 6,123 m² plant specimen garden includes the medicinal plants that are considered important for the students’ education. This garden serves a variety of purposes, including maintenance of plant lineages; research on plant breeding and cultivation; collection and cultivation of medicinal plants native to Japan as well as introduced from overseas; research on medicinal plant ingredients from the standpoints of chemistry, pharmacology, biosynthesis, plant physiology, and pharmacognosy; and research on the medicinal plant cultivation and maintenance. The grounds of the Experimental Station also encompass a greenhouse, administration building, and laboratory building. At present, about 250 varieties of plants are under cultivation. Each year, 3rd-year students receive practical training in the plant specimen garden during the summer session. In 1982, the laboratory for medicinal plant studies was set up within the building in Hongo Campus and have continued research until now. The University Museum, The University of Tokyo (Hongo Campus) houses a Pharmaceutical Sciences Division on its first floor, where a large number of specimens – mainly crude drugs and medicinal plants – are stored and managed. In October 2004, the first rooftop herb garden, with an area of approximately 100 m², was created on the rooftop of the auditorium of Pharmaceutical Sciences Research Building for enabling the students to come into close contact with medicinal plants. Several dozen varieties of medicinal plants are cultivated in light soil with a depth of about 60 cm, equipped with an automatic irrigation system.
